The US leads the way in electric vehicle adoption, but Canada's car industry is yet to catch on with just three per cent of the nation's vehicle sales originating from electric vehicles in 2013, according to a study from McAfee. "The current electric vehicle industry consists of well-funded start-ups like Tesla and small numbers of owner-operators," said McAfee's Rick Hartwig, in a statement. "The technologies are in place, just not from a vehicle provider perspective." By the year 2020, McAfee projects electric vehicles will make up 25 per cent of sales in Canada, and by 2030, the continent's leading car supplier will sell more electric vehicles than gas-powered vehicles. According to McAfee's forecast, by the year 2030 electric vehicles will account for more than one-third of all vehicles sold in Canada (33 per cent), while gas-powered vehicles will make up the bulk of sales (64 per cent). The only car companies currently making vehicles that are billed as electric in Canada are Toyota, which sells the RAV4 EV, and General Motors, which sells the Chevrolet Volt. "Our forecast assumes current policy will stay in place, meaning less government handouts for electric car producers. The assumption is that government will stay out of the electric vehicle business, and corporations will follow their lead," McAfee said. As one of Canada's largest auto suppliers, General Motors is actually included in the McAfee's electric vehicle forecast in 2030 – an important development, considering the automaker once considered dabbling with electric vehicles in the future. After the GM and Ford layoffs in 2009, the automaker eliminated the Volt and other electric vehicles from its product line. This application relates to the operation of non-volatile memory systems such as NAND flash memory systems. Solid-state memory capable of nonvolatile storage of charge, particularly in the form of EEPROM and flash EEPROM packaged as a small form factor card, has become the storage of choice in a variety of mobile and handheld devices, notably information appliances and consumer electronics products. Unlike RAM (random access memory) that is also solid-state memory, flash memory is non-volatile, and retains its stored data even after power is turned off. Also, unlike ROM (read only memory), flash memory is rewritable similar to a disk storage device. In spite of the higher cost, flash memory is increasingly being used in mass storage applications. Conventional mass storage

Designs for wireless networks are being continuously updated as scientists and engineers strive to improve the overall performance of these networks. For example, if the amount of signal interference generated by a wireless network increases, throughput and the quality of service of the network decreases. Consequently, measures to prevent interference and/or maximize the amount of usable signal are taken. As one example, a wireless device may operate at a frequency that is adjacent to another frequency that is used by another device. In these situations, a different frequency may be used by the other device and the interference is likely to occur. Designing a wireless network to avoid interference is, however, difficult, particularly if the interfering signals are multiple-access signals. A single-access signal is the signal transmitted by a wireless device for a single purpose (e.g., with the signal) being received and used by a first receiving device; whereas a multiple-access signal is transmitted by a wireless device for multiple purposes (e.g., with the signal) being received and used by multiple receiving devices. For example, a single-access signal may be a signal transmitted from a second wireless device (with the signal) to a first wireless device (with the signal); whereas a multiple-access signal may be a signal transmitted from a second wireless device (with the signal) to multiple first wireless devices (with the signal). What is needed,

then, are techniques for designing a wireless network that avoid interference between wireless devices. Progression of HIV-1 resistance to nucleoside and non-nucleoside analogues is variable among different regions, suggesting that molecular epidemiology studies could be useful for regional surveillance. The development of resistance to antiretroviral therapy in patients with HIV-1 infections, resulting in therapeutic failure, is variable and depends upon the presence of mutations in the viral reverse transcriptase (RT) and other gene regions such as the protease (PR) and integrase (IN), as well as variations in viral load. These variations contribute to local variations in the frequency of cross-resistance. The knowledge of which mutations exist and their prevalence can provide important information for clinical decision-making. The question of whether new mutations, or the existence of mixed infections, are more likely to appear in certain regions, has not been adequately addressed. We examined, for a total of 1006 samples from 454 patients who were being treated in 17 European countries, whether there was regional variability in the emergence of nucleoside RT inhibitor (NRTI) and non
